

LAB #13

OPERATIONS ON FILES

Objective

Study the features of I/O system calls (open, read, write, close).

Exercises

1. Write few lines about what did you learn after running Programs 3 and Program 4.

After running Program 3 and Program 4, I observed that the file contents were no longer mixed together. This happened because both programs used the lockf() system call to lock the file before writing.

When one process acquired the lock, the other process had to wait until the first process completed its writing operation. As a result, all the characters written by one program appeared together in the file, followed by the characters written by the second program.

I learned that file locking prevents race conditions and protects shared files from data corruption when multiple processes access the same file simultaneously. It ensures data consistency and synchronization between processes.
